List of largest stars

Below are **lists of the largest stars** currently known, ordered by radius and separated into categories by galaxy. The unit of measurement used is the radius of the Sun (approximately 695,700 km; 432,300 mi).[1]

Overview

Although red supergiants are often considered the largest stars, some other star types have been found to temporarily increase significantly in radius, such as during LBV eruptions or luminous red novae. Luminous red novae appear to expand extremely rapidly, reaching thousands to tens of thousands of solar radii within only a few months, significantly larger than the largest red supergiants.[2]

Some studies use models that predict high-accreting Population III or Population I supermassive stars (SMSs) in the very early universe could have evolved "red supergiant protostars". These protostars are thought to have accretion rates larger than the rate of contraction, resulting in lower temperatures but with radii reaching up to many tens of thousands of $R_{\odot}$, comparable to some of the largest known black holes.[3][4][5]

Angular diameters

The angular diameters of stars can be measured directly using stellar interferometry. Other methods can use lunar occultations or from eclipsing binaries, which can be used to test indirect methods of finding stellar radii. Only a few supergiants can be occulted by the Moon, including Antares and 119 Tauri. Examples of eclipsing binaries are Epsilon Aurigae (Almaaz), VV Cephei, and V766 Centauri (HR 5171). Angular diameter measurements can be inconsistent because the boundary of the very tenuous atmosphere (opacity) differs depending on the wavelength of light in which the star is observed.

Uncertainties remain with the membership and order of the lists, especially when deriving various parameters used in calculations, such as stellar luminosity and effective temperature. Often stellar radii can only be expressed as an average or be within a large range of values. Values for stellar radii vary significantly in different sources and for different observation methods.[6]

All the sizes stated in these lists have inaccuracies and may be disputed. The lists are still a work in progress and parameters are prone to change.

Caveats

Various issues exist in determining accurate radii of the largest stars, which in many cases do display significant errors. The following lists are generally based on various considerations or assumptions; these include:

- Stellar radii or diameters are usually derived only approximately using the Stefan–Boltzmann law for the deduced stellar luminosity and effective surface temperature.
- Stellar distances, and their errors, for most stars, remain uncertain or poorly determined.
- Many extended supergiant atmospheres also significantly change in size over time, regularly or irregularly pulsating over several months or years as variable stars. This makes adopted luminosities poorly known and may significantly change the quoted radii.
- Other direct methods for determining stellar radii rely on lunar occultations or from eclipses in binary systems. This is only possible for a very small number of stars.[7]
- Many distance estimates for red supergiants come from stellar cluster or association membership, because it is difficult to calculate accurate distances for red supergiants that are not part of any cluster or association.
- In these lists are some examples of extremely distant extragalactic stars, which may have slightly different properties and natures than the currently largest known stars in the Milky Way. For example, some red supergiants in the Magellanic Clouds are suspected to have slightly different limiting temperatures and luminosities. Such stars may exceed accepted limits by undergoing large eruptions or changing their spectral types over just a few months (or potentially years).[8][9]

List of the largest known stars in the Magellanic Clouds

Star name	Solar radius ($R_\odot$)	Galaxy	Method[a]	Notes
Theoretical limit of star size (Large Magellanic Cloud)	≳1,550[11]		L/T_{eff}	Estimated by measuring the fraction of red supergiants at higher luminosities in a large sample of stars. Assumes an effective temperature of 3,545 K. Reported for reference
WOH G64 A	1,540[12][13][14][15][16] ± 77[12]	Large Magellanic Cloud	L/T_{eff}	Once thought to have become a smaller yellow hypergiant, due to its transition from semi-regular to irregular variability in 2014.[117] Recent data show it remains a red supergiant, affected by a companion star.[118] Possibly the largest known star.[12][13][17][14]

Stars with poorly-defined radii

List of the possible largest known stars

Star name	Solar radius (Template:Solar radius)	Galaxy	Group	MethodTemplate:Efn	Notes
Stephenson 2 DFK 1 *(St2-18)*	2,200 (± ~1,100)[194]	Milky Way	Local Group	L/T_{eff}	Distance used to calculate radius could have an uncertainty of over 50% based on discrepancies between radial velocity-based and trigonometrically determined distances for other stars.[194] Its spectral energy distribution is also unusual, and its 2MASS J and H-band fluxes suggest an effective temperature that is inconsistent with the star being a red supergiant and would require a very high extinction, which would make its luminosity much higher than has ever been accurately observed in a red supergiant and therefore may be a foreground star unrelated to the cluster thus making it smaller. This may also be supported by the fact that its radial velocity is slightly offset from that of the cluster, although this has been contested.[18][195]
NML Cygni	<Template:ValTemplate:Efn	Milky Way	Local Group	AD	Surrounding dusty region is very complex making the radius hard to determine.[196]

Largest stars by apparent size

The following list include the largest stars by their apparent size (angular diameter) as seen from Earth. The unit of measurement is the milliarcsecond (mas), equivalent to Template:Val. Stars with angular diameters larger than 13Template:Nbspmilliarcseconds are included.

1. Methods for calculating the radius:
   - AD: radius calculated from angular diameter and distance
   - L/T_{eff}: radius calculated from bolometric luminosity and effective temperature
   - SEIS: radius obtained from seismic data
   - OD: radius obtained from optical depth
